

Agent Credit Protocol

Credit infrastructure for autonomous commerce

AI agents and AI-native businesses are starting to transact programmatically. Payments are the first primitive. Credit is the next.

HACKATHON EXPLORATION -> DISCIPLINED WEDGE

Agents can pay. They cannot get credit.

EMERGING AGENT COMMERCE HAS NO NATIVE ANSWER FOR

- Working capital before revenue arrives
- Spend limits for autonomous workflows
- Postpaid / net-7 / net-30 API usage
- Underwriting based on agent activity
- Repayment and default handling
- Capital providers who want exposure

PAYMENT RAILS ANSWER

How does an agent pay?

AGC ANSWERS

When should an agent be trusted with spending power?

Payments let agents transact. Credit lets agents operate.

The transaction layer is arriving. The credit layer is missing.

1 AI workflows are becoming economic actors

Agents increasingly buy APIs, data, tools, compute, and execution services.

2 Payment rails are becoming programmable

HTTP-native payment protocols make per-request payments viable for software and agents.

3 Onchain rails make credit state observable

Utilization, repayment, reserves, underwriter capital, and defaults can be measured directly.

The wedge starts with AI-native businesses that operate agent workflows. Over time, the credit layer moves closer to the agent itself.

Start with AI-native businesses, then move down the autonomy stack.

INITIAL PRODUCT

USDC credit lines for AI-native businesses and agent workflows.

V1 PRINCIPLE

No new money token required. Prove demand, repayment, and underwriting first.

FIRST USE CASES

- API / tool / compute spend
- Agent marketplace budgets
- x402-style postpaid billing
- Working capital for AI micro-businesses
- Revenue-backed credit for autonomous workflows
- Controlled spending power, not open-ended lending

The credit control plane for agentic commerce

Payments move money. AGC underwrites agent activity.

MARKET MAP

Category	What they solve	What is missing
Payment rails	How agents pay	Credit, limits, underwriting
Wallet infra	Settlement + custody	Borrower risk model
DeFi lenders	Collateralized liquidity	Agent cashflow underwriting
Private credit / RWA	Institutional borrowers	Agent-native workflows
AGC	Credit decisions + control plane	Starting narrow, then compounding

MOAT

The moat is the agent credit graph.

agent spend -> revenue -> utilization ->
repayment -> default data -> better
underwriting -> cheaper capital -> more
borrowers -> more data

The underwriting graph is the wedge.

From hackathon exploration to live credit network

WHAT EXISTS NOW

- Solana devnet prototype
- Credit facility mechanics
- Underwriter deposits
- Borrow / draw / repay / default flows
- Policy simulator + dashboard

12-WEEK PLAN

1-2

customer discovery + competitor map

3-4

USDC credit-line MVP

5-6

x402 / API spend integration prototype

7-8

risk dashboard + underwriting telemetry

9-10

first sandbox pilots

11-12

whitepaper, live demo, fundraising narrative

Join CyberFund Monastery and build the first credit network for agentic commerce.
